

Purpose

The **LOK-TEST** system is used to obtain a reliable estimate of the in-place compressive strength of concrete in newly cast structures in accordance with the pullout test method described in ASTM C900, BS 1881:207, or EN 12504-3. **LOK-TEST** can be used for:

- Determining whether in-place concrete strength is sufficient for timing of early and safe loading operations, such as due to formwork removal or application of prestressing.
- Determining whether the in-place strength is sufficient for terminating curing and thermal protection.
- Quickly evaluating the quality of the critical cover layer protecting the reinforcement in the finished structure.
- Evaluating the quality of the critical cover layer protecting the reinforcement in the finished structure.

Principle

An insert with a steel disc, 25 mm in diameter at a depth of 25 mm, is cast into concrete either by attaching it to formwork before placing concrete or by inserting it manually into the fresh concrete. Various **LOK-TEST** inserts are available.

Once the concrete has hardened, the disc is pulled centrally against a 55 mm diameter counter pressure ring bearing on the surface. The force \mathbf{F} required to pullout the insert is measured while the concrete in the strut between the disc and the counter pressure ring is subjected to a compressive load. Therefore, the pullout force \mathbf{F} is related directly to the compressive strength.

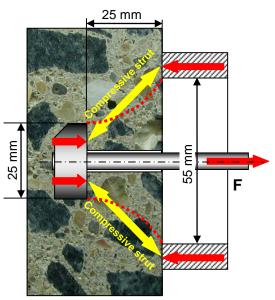

Loading is performed either to a required force, in which case the test is nondestructive, or to the peak-load, which results in a slightly raised, 55-mm diameter circular crack on the surface.

Correlation and Accuracy of Estimated Strength

LOK-TEST provides an immediate and accurate estimate of in-place strength because the peak pullout force has a well-defined correlation to compressive strength measured using standard cylinders or cubes. Test methods to estimate compressive strength like rebound hammer (Schmidt hammer), ultrasonic pulse velocity or Windsor probe, require to develop particular correlations for every concrete mixture. By contrast, the more than 30 years of correlation experience with **LOK-TEST** and **CAPO-TEST** from all over the world indicates that **one general correlation** can be applicable for all normal density concrete mixtures. A significantly different correlation, however, has been found for concrete made with lightweight (low density) aggregate.

The general correlations between pull-out force and standard compressive strength shown in the following figures are product of about 30 major independent studies and provide sufficient accuracy for normal density concrete mixtures. The studies were performed by various laboratories in Denmark, Sweden, Norway, Holland, Canada, the United States, Poland, and England.^{1,2} It has been shown that these general correlations are not affected by types of cementitious materials, water-cementitious materials ratio (w/cm), maturity, use of self-consolidating concrete, normal amounts of air entrainment, use of admixtures, curing conditions, stresses in the structure, rigidity of the member, carbonation, as well as shape, type, and size of aggregate up to 38 mm.

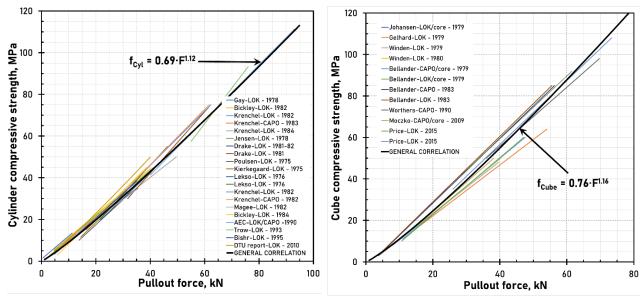

Other correlations have been established, such as the large project at the University of Liverpool³ aimed at methods for assessing early-age strength and whose efforts led to a best practice guide by the British Cement Association⁴ in which the pullout test is recommended for assessing early-age strength

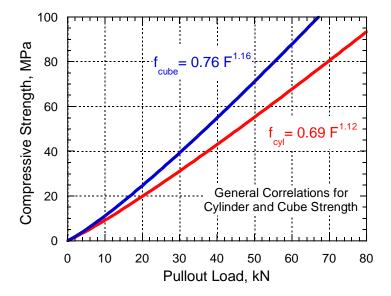

in new construction. In this British research, the general correlation between LOK-TEST and 150 mm cube strength was confirmed for the normal-density concrete mixtures investigated.

At the 95 % confidence level and for an average of 4 tests, the estimated compressive strength based on the **LOK-TEST** and the general correlations indicated is within \pm 6 % of the strength measured from tests of standard specimen (cylinders or cubes) for a maximum aggregate size of 38 mm. The coefficient of variation of individual **LOK-TEST** results is about 6 to 8 % for normal density concrete.

The best-fit curve to 18 correlations between pullout force and the compressive strength of 150 x 300 mm (6 x 12 in.).

The best-fit curve to 12 correlations between pullout force and compressive strength of 150 mm (6 in.) cubes

The reason why the failure mechanism of LOK and CAPO tests performed in accordance with ASTM C900 or EN 12504-3 gives these very robust correlations is discussed in references 5 and 6. Project specifications, however, may require development of mixture specific correlations. In this case, ACI 228.1R gives guidance on how to develop such relationships⁷.

LOK-TEST inserts are supplied in four different configurations and in two strength classes: (normal strength) 0 to 50 kN and (high strength) 0 to 100 kN pullout force.

- L-40 and L-41: Control inserts for nailing to wooden formwork. The formwork has to be removed before testing.
- L-42 and L-43: Early stripping inserts, with a steel plate for attachment to a removable plug through a porthole in the formwork, for use if testing is performed before the formwork is removed.
- L-45 and L-46: Disc and stem, only, for replacement of used inserts.
- L-49 and L-50: Floating inserts for insertion into the top surface of newly cast concrete.

High strength, 0 to 100 kN

Example Applications

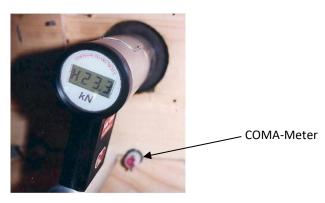

LOK-TEST being performed on a wall for quality control of the finished structure. "H" on the display shows the highest pullout force. The L-40 Insert is used.

Testing for in-place quality control on a slab. The L-49 floating insert is used. Maturity was measured with the **COMA-Meter**, shown in front of technician's knee.

LOK-TEST performed from the bottom of a slab, through the formwork, for safe and early form removal. The L-42 early stripping insert was used with the L-44 steel plate attached to a removable plug through a porthole in the formwork. **COMA-Meters** are used for timing of the **LOK-TEST**.

LOK-TEST Specifications

- Battery powered handheld hydraulic pulling machine with robust steel-aluminum body
- Digital display resolution = 0.1 kN
- Maximum force: 100 kN
- Maximum stroke: 6 mm
- Accuracy of measurements: ± 2%
- Operating conditions: -10 to 50°C, max. RH = 95%
- Memory capacity: 512 measurements (peak-value, time and date of testing)
- AMIGAS Software for PC communication and printout

LOK-TEST Ordering Numbers

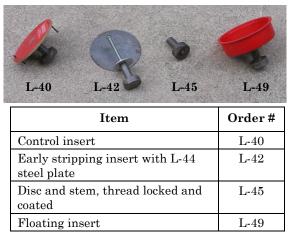

The L-11-1 pull machine can be also used for CAPO-TEST and BOND-TEST. See their Technical Data Sheets.

LUK-IESI L-II KIU	
Item	Order #
Hydraulic pull machine with	L-11-1
electronic gauge	
AMIGAS Printout software	L-13
Cable for printout	L-14
Centering plate	L-15
Coupling	L-16
Pull bolt	L-17
Stem removal tool	L-18
Bolt handle	L-19
Adjustable pliers	L-20
Oil refilling cup	L-24
Oil refilling bottle	L-25
Large screwdriver	C-149
Small screwdriver	C-157
Calibration table	L-32
Manual	L-33
Attaché case	L-34

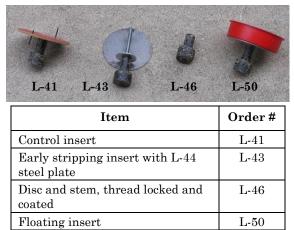

LOK-TEST L-11 Kit

Inserts

Normal strength, 0 to 50 kN

High strength*, 0 to 100 kN

*For testing high strength inserts, a special high-strength pull bolt with flange is needed, L-17-1, along with the high-strength coupling device C-141.

Inserts may be re-used provided the discs are thread locked to the stems and coated with a coating agent, **L-29**, before re-use. For complete pulling out of discs from the concrete, a separate travel ring, L-26, is available.

Load Verification Unit

The calibration of a pull machine is recommended to be verified at least once a year, after servicing or after repair.

The **L-30** Load Verification Unit has a working range of 0 to 100 kN and ensures that the load displayed by the pull machine is within 2 % of the actual load, as required by ASTM C900. The load is displayed to the nearest 0.1 kN.
